AV Profit

Bijesh Mishra, Ph.D.

2024-10-11

Table of contents

Analysis in this file start by loading data saved after simulating tomato and strawberry AV profits. See simulation file for more details. The result tables I have here are quite big. Results are summarized in separate excel files.

1 Setting Up

1.1 Housekeeping

```
# #| echo: TRUE
rm(list = ls()) # Clean the environment.
options(
  warn=0, # Warnings. options(warn=-1) / options(warn=0)
  scipen=999 # No scientific notations.
  )
```

1.2 Working directory

Codes and output are suppressed. Errors and warnings are visible. No warning and no error means code is working as it should.

1.3 Load libraries

```
library(tidyverse, warn.conflicts = FALSE, quietly = TRUE)
```

```
-- Attaching core tidyverse packages ------------------------ tidyverse 2.0.0 --
v dplyr     1.1.4     v readr     2.1.5
v forcats   1.0.0     v stringr   1.5.1
v ggplot2   3.5.1     v tibble    3.2.1
v lubridate 1.9.3     v tidyr     1.3.1
v purrr     1.0.2
-- Conflicts ------------------------------------------ tidyverse_conflicts() --
x dplyr::filter() masks stats::filter()
x dplyr::lag()    masks stats::lag()
i Use the conflicted package (<http://conflicted.r-lib.org/>) to force all conflicts to becom
```

```r
library(psych, warn.conflicts = FALSE, quietly = TRUE)
library(likert,  warn.conflicts = FALSE, quietly = TRUE)
library(mice,  warn.conflicts = FALSE, quietly = TRUE)
library(openxlsx2, warn.conflicts = FALSE, quietly = TRUE)
library(ggpubr, warn.conflicts = FALSE, quietly = TRUE)
library(gmodels,  warn.conflicts = FALSE, quietly = TRUE)
library(reshape2, warn.conflicts = FALSE, quietly = TRUE)
library(arrow, warn.conflicts = FALSE, quietly = TRUE)
library(plot3D, warn.conflicts = FALSE, quietly = TRUE)
library(plotly, warn.conflicts = FALSE, quietly = TRUE)
library(lattice, warn.conflicts = FALSE, quietly = TRUE)
library(purrr, warn.conflicts = FALSE, quietly = TRUE)
library(furrr, warn.conflicts = FALSE, quietly = TRUE)
library(pheatmap, warn.conflicts = FALSE, quietly = TRUE)
library(grid, warn.conflicts = FALSE, quietly = TRUE)
library(data.table, warn.conflicts = FALSE, quietly = TRUE)
library(parallel, warn.conflicts = FALSE, quietly = TRUE)
```

2 Import data

Import necessary data.

2.1 Tomato AV

Parameters defining agrivoltaic systems:

- sprop = proportion of solar in agrivoltaic system (0 to 1 in 0.5 increment.) Length = 21.
- panels = number of solar panels. Length = 16. Some sprop have same number of panels.
- al_regs = four regions of Alabama. Northern, Central, Black Belt, Southern. Length = 4.
- array = Solar array; Sun tracking (Tracking) and non-tracking (Fixed). Length = 2.
- elecprc = electricity price (1 cents to 6 cents). Length = 6.
- height = clearance height of solar panels. 4.6 ft., 6.4 ft., and 8.2 ft. Length = 3.
- yldvar = crop yield variation (10% to 200%) = Length 21.
- yield = crop yield variation based on yldvar. (same as yldvar) = Length = 21.

Calculated results using above parameters:

- dc_kw = DC system size (kW) See PVWatts® Calculator.
- energy = total energy generated from solar system. See: PVWatts® Calculator.
- capex = AV system capex per kW. See: Capex Cost for AV table 1 and table 3.
- ttlcost = total solar system cost in AV. See: Capex Cost for AV table 1 and table 3.
- anncost = annualized total cost.
- moncost = monthly total cost.
- price = crop yield price per bucket.
- eprofit = profit from electricity.

Result of Interests:

- eannprof = annualized total profit from electricity.
- emonprof = monthly total profit from electricity.
- profit = profit from crops.
- tav_profit = total profit from solar and tomato.

```
tav_profit <- as.data.frame(
  read_feather(file = "Data/tav_profit.feather")
  )
dim(tav_profit)
```

```
[1] 814968     29
```

2.1.1 Calculate tavp_wocp

- Profit at 100% crop yield at their respective price is subtracted from tav_profit.
- tavp_wocp = tav_profit - profit from 100% crop at their respective prices. This variable gives an idea where av profit stands in relation to crop profit. It helps to identify relative profitability of agrivoltaic system compared to crop only.

```r
# Calculate the profit:
# Step 1: Filter the dataframe to get the unique profit values for each price when yldva
unique_profits <- unique(tav_profit[tav_profit$yldvar == 1,
                                    c("price", "profit")])

# Step 2: Create a lookup table for unique profits by price
profit_lookup <- setNames(unique_profits$profit,
                          unique_profits$price)

# Step 3: Create the new variable tavp_wocp by subtracting the unique profit from tav_pr
tav_profit$tavp_wocp <- mapply(function(
    tav_profit,
    price
    ) {
  profit_to_subtract <- ifelse(
    price %in%
      names(profit_lookup),
    profit_lookup[as.character(price)], 0)
  return(tav_profit - profit_to_subtract)
}, tav_profit$tav_profit, tav_profit$price)
unique_profits # 7 Prices give 7 Profits at 100% Yield.
```

```
    price    profit
11     17  5539.383

4.8 Plotting Strawberry Profit by Panels

You can see plot breakdown based on yield variation, crop price, and electricity price. You can see variation for all solar proportion in one facet of the chart. Each facet of the chart contain av profit three heights of solar panels, four regions of AL, two array types.

```r
combinations <- expand.grid(
  yldvar = c(0, 0.1, 0.3, 0.5, 0.7, 1, 1.20, 1.5, 1.80, 2), # Yield
  price = c(3, 6, 9), # Strawberry price
  elcprc = c(0.03, 0.04, 0.05) # Electricity price
)

# Iterate over the combinations and create the plots
for (combo in seq_len(nrow(combinations))) {
  filtered_data <- sbav_profit %>%
```

```r
  filter(
    yldvar == combinations$yldvar[combo],
    price == combinations$price[combo],
    elcprc == combinations$elcprc[combo]
  )
# If by panel, put panels below in color and group.

4.9 Plotting Strawberry Profit by Yields

You can see plot breakdown based on solar proportion, crop price, and electricity price. You can see variation for all crop yield variation in one facet of the chart. Each facet of the chart contain av profit three heights of solar panels, four regions of AL, two array types.

```
combinations <- expand.grid(
  sprop = c(0, 0.25, 0.50, 0.75, 1.00), # Solar proportion
  price = c(3, 6, 9), # Strawberry price
  elcprc = c(0.03, 0.04, 0.05) #Electricity price
)

# Iterate over the combinations and create the plots
for (combo in seq_len(nrow(combinations))) {
  filtered_data <- sbav_profit %>%
    filter(
      sprop == combinations$sprop[combo],
      price == combinations$price[combo],
      elcprc == combinations$elcprc[combo]
    )
  # If by yield, put yield below in color and group.
  sbav_yv_plot <- ggplot(data = filtered_data,
                        mapping = aes(x = al_regs,
